# Shor's algorithm

## Polynomial-Time Algorithms for Prime Factorization and Discrete Logarithms on a Quantum Computer

Proc. 35th Annual Symp. on Foundations of Computer Science, IEEE Computer Society Press, pp. 124-134 (1994)

was a turning point in quantum computing for its spectacular decrease of the **time complexity** of factoring from  $\mathcal{O}(e^{\sqrt[3]{n}})$  to  $\mathcal{O}(n^3 \log n)$ , with potential impact in cryptography.

# Factorization

In this famous 1994 paper, Peter Shor proved that it is possible to factor a  $n$ -bit number in time that is **polynomial** to  $n$ .

## The factorization problem

Given an integer  $n$ , find positive integers  $p_1, p_2, \dots, p_m, r_1, r_2, \dots, r_m$  such that

- Integers  $p_1, p_2, \dots, p_m$  are distinct **primes**;
- and,  $n = p_1^{r_1} \times p_2^{r_2} \times \dots \times p_m^{r_m}$ .

Note that one may assume  $n$  to be odd and contain at least two distinct odd prime factors (why?)

# Factorization

Since the **test for primality** can be done **classically** in polynomial time, the **factoring problem** can be **reduced** to  $\mathcal{O}(\log n)$  instances of the following problem:

## The odd non-prime-power integer splitting problem

Given an odd integer  $n$ , with at least two distinct prime factors, compute two integers

$$1 < n_1 < n \quad \text{and} \quad 1 < n_2 < n$$

$$\text{st } n = n_1 \times n_2$$

# Factorization

Miller proved in 1975 that this problem **reduces probabilistically** to another problem whose solution resorts to the **eigenvalue estimation problem**, already studied.

## The order-finding problem

Given two coprime integers  $a$  and  $n$  (i.e. st  $\gcd(a, n) = 1$ ), find the **order of  $a$  modulo  $n$** .

## Preliminaries: Modular arithmetic

Consider the group of integers modulo  $n$ ,

$$\mathcal{Z}_n = (\{0, 1, 2, \dots, n-1\}, \times_n, 1, {}^{-1})$$

For two integers  $x$  and  $y$  we write

$$x \equiv y \pmod{n} \text{ iff } \text{rem}(x, n) = y$$

or, equivalently,  $\text{rem}(x - y, n) = 0$ , where  $\text{rem}(a, b)$  is the remainder of the integer division of  $a$  by  $b$ .

### Examples

$$5 \equiv 0 \pmod{5} \text{ and } 6 \equiv 1 \pmod{5}$$

# Preliminaries: Modular arithmetic

## Definition

For co-prime integers  $a < n$  the **order of  $a \pmod{n}$**  is the smallest integer  $r > 0$  s.t.  $a^r \equiv 1 \pmod{n}$

## Example

If  $N = 5$  the sequence  $3^0, 3^1, 3^2, 3^3, 3^4, 3^5, 3^6, \dots$  leads to the sequence  $1, 3, 4, 2, 1, 3, 4, \dots$ . Thus, Order of  $3 \pmod{5}$  is thus 4

## Exercise

What is the order of  $2 \pmod{11}$ ?

# The problem

## The order-finding problem

Given two coprime integers  $a$  and  $n$  (i.e. st  $\gcd(a, n) = 1$ ), find the **order of  $a$  modulo  $n$** , i.e. the smallest positive integer  $r$  such that

$$a^r \equiv 1 \pmod{n}$$

- Classically, this problem can be difficult for large integers.
- In a quantum computer, however, it can be solved efficiently via the **quantum eigenvalue estimation** algorithm.

## Strategy: The eigenvalue approach

Recall the eigenvalue estimation circuit:

Need to choose suitable  $U$  and  $|\psi\rangle$  to disclose the order

## Strategy: The eigenvalue approach

Take co-prime integers  $a < n$

Let  $m = \lceil \log_2 n \rceil$  and define  $U_a : \mathbb{C}^{2^m} \rightarrow \mathbb{C}^{2^m}$

$$U_a(|q\rangle) = |\text{rem}(qa, n)\rangle \quad \text{for } 0 \leq q < n$$

$$U_a(|q\rangle) = |q\rangle \quad \text{for } q \geq n$$

### Exercise

Show  $U_a$  is unitary.

### Exercise

Show that  $U_a |\text{rem}(a^n, n)\rangle = |\text{rem}(a^{n+1}, n)\rangle$

Next step is to identify **suitable eigenvectors**.

## A first attempt (starting with an example)

For  $n = 5$ , sequence

$$3^0, 3^1, 3^2, 3^3, 3^4, 3^5, 3^6, \dots$$

leads to 1, 3, 4, 2, 1, 3, 4,  $\dots$ , thus the order  $r$  of 3 (mod 5) is 4.

Thus, compute

$$\begin{aligned} U_a \left( \frac{1}{\sqrt{r}} (|1\rangle + |3\rangle + |4\rangle + |2\rangle) \right) \\ &= U_a \left( \frac{1}{\sqrt{r}} \sum_{i=0}^{r-1} |\text{rem}(3^i, 5)\rangle \right) \\ &= \frac{1}{\sqrt{r}} \sum_{i=0}^{r-1} |\text{rem}(3^{i+1}, 5)\rangle \\ &= \frac{1}{\sqrt{r}} (|3\rangle + |4\rangle + |2\rangle + |1\rangle) \\ &= \frac{1}{\sqrt{r}} (|1\rangle + |3\rangle + |4\rangle + |2\rangle) \end{aligned}$$

... to conclude that his state is an **eigenvector** of  $U_a$

## A second attempt

The previous example resorts to the equation

$$U_a \left( \frac{1}{\sqrt{r}} \sum_{i=0}^{r-1} |\text{rem}(a^i, n)\rangle \right) = \frac{1}{\sqrt{r}} \sum_{i=0}^{r-1} |\text{rem}(a^i, n)\rangle$$

Unfortunately, the corresponding eigenvalue is **1** ...  
... which does not disclose any information about  $r$ !

Need to find eigenvectors with **more informative eigenvalues**.

## A second attempt

Since  $a^r = 1 \pmod{n}$ ,

$$U_a^r(|q\rangle) = |\text{rem}(qa^r, n)\rangle = |q\rangle$$

i.e.  $U_a$  is the  $r$ th root of the identity operator  $I$ , i.e.  $(U_a)^r = I$ .

It can be shown that the eigenvalues  $\lambda$  of such an operator satisfy  $\lambda^r = 1$ , i.e. they are the  $r$ th root of 1, which means they take the form  $e^{i2\pi\frac{k}{r}}$ , for some integer  $k$ .

In the previous example,  $1 = e^{i2\pi\frac{0}{r}}$

## A second attempt

Let us consider a different state:

$$|\psi_1\rangle = \frac{1}{\sqrt{r}} \sum_{i=0}^{r-1} \omega^{-i} |\text{rem}(a^i, n)\rangle$$

where  $\omega = e^{i2\pi \cdot \frac{1}{r}}$  (division of the unit circle in  $r$  slices)  
a.k.a. the  $r$  roots of unity

$$\begin{aligned} & U_a \left( \frac{1}{\sqrt{r}} \sum_{i=0}^{r-1} \omega^{-i} |\text{rem}(a^i, n)\rangle \right) \\ &= \frac{1}{\sqrt{r}} \sum_{i=0}^{r-1} \omega^{-i} |\text{rem}(a^{i+1}, n)\rangle \\ &= \frac{1}{\sqrt{r}} \sum_{i=0}^{r-1} \omega \omega^{-(i+1)} |\text{rem}(a^{i+1}, n)\rangle \\ &= \omega \left( \frac{1}{\sqrt{r}} \sum_{i=0}^{r-1} \omega^{-(i+1)} |\text{rem}(a^{i+1}, n)\rangle \right) \\ &= \omega \left( \frac{1}{\sqrt{r}} \sum_{i=0}^{r-1} \omega^{-i} |\text{rem}(a^i, n)\rangle \right) \end{aligned}$$

## A second attempt

The calculation in the previous slide shows that

$$U_a |\psi_1\rangle = \omega |\psi_1\rangle$$

So if we feed the **quantum eigenvalue estimation circuit** with  $U_a$  and  $|\psi_1\rangle$  we obtain an approximation of  $\frac{1}{r}$  with a good success probability ( $\geq \frac{4}{\pi^2} \approx 0.4$ ).

### Exercise

Formally justify all the steps in that calculation.

### Exercise

Would a similar conclusion pop out if our starting state was

$$|\psi_k\rangle = \frac{1}{\sqrt{r}} \sum_{i=0}^{r-1} \omega^{-ik} |\text{rem}(a^i, n)\rangle$$

## A third attempt

However ...

Without knowing  $r$  we do not know how to prepare  $|u_1\rangle$ , or, in general  $|u_k\rangle$ .

Fortunately, it is **not** necessary!

Instead of preparing an eigenstate corresponding to an eigenvalue  $e^{i2\pi\frac{k}{r}}$  for a randomly selected  $k \in \{0, 1, \dots, r-1\}$ , it suffices to prepare a **uniform superposition of the eigenstates**

Then the **eigenvalue estimation algorithm** will compute a **superposition of these eigenstates entangled with estimates of their eigenvalues**.

Thus, when a measurement is performed, the result is an **estimate of a random eigenvalue**.

### Question

How to prepare such a superposition without knowing  $r$ ?

## A third attempt

Define

$$|\psi\rangle = \frac{1}{\sqrt{r}} \sum_{k=0}^{r-1} |\psi_k\rangle$$

with  $|\psi_k\rangle = \frac{1}{\sqrt{r}} \sum_{i=0}^{r-1} \omega^{-ik} |\text{rem}(a^i, n)\rangle$ .

### Exercise

Show that  $U_a |\psi_k\rangle = \omega^k |\psi_k\rangle$ .

Now observe that

$$|\text{rem}(a^i, n)\rangle = |1\rangle \text{ iff } \text{rem}(i, r) = 0$$

Thus, the amplitude of  $|1\rangle$  in the above state is the sum over the terms for which  $i = 0$

(because  $i$  takes values in  $[0, r-1]$  and must be a multiple of  $r$ )

$$\frac{1}{\sqrt{r}} \frac{1}{\sqrt{r}} \sum_{k=0}^{r-1} e^{-i2\pi \frac{k}{r} 0} = \frac{1}{r} \sum_{k=0}^{r-1} 1 = 1$$

## A third attempt

Thus, if the amplitude of  $|1\rangle$  is **1**, this means that the amplitudes of all other basis states are **0**, yielding

$$\frac{1}{\sqrt{r}} \sum_{k=0}^{r-1} |u_k\rangle = |1\rangle$$

Therefore, we have defined a **superposition of eigenvectors** that is equal to  $|1\rangle$ .

## Summing up

Thus, the eigenvalue estimation algorithm maps

$$|0\rangle|1\rangle = |0\rangle \left( \frac{1}{\sqrt{r}} \sum_{k=0}^{r-1} |u_k\rangle \right) = \frac{1}{\sqrt{r}} \sum_{k=0}^{r-1} |0\rangle |u_k\rangle \mapsto \frac{1}{\sqrt{r}} \sum_{k=0}^{r-1} |\tilde{\phi}_k\rangle |u_k\rangle$$

where each  $|\tilde{\phi}_k\rangle$  is the best  $n$ -bit approximation of  $\frac{k}{r}$  with probability  $\geq \frac{4}{\pi^2}$

But how to extract  $r$  from  $|\tilde{\phi}_k\rangle$ ?

To estimate  $r$  one resorts another result in [number theory](#) ...

## Estimating $r$

**Theorem:** Let  $r$  be a positive integer, and take integers  $k_1$  to  $k_2$  selected independently and uniformly at random from  $\{0, 1, \dots, r-1\}$ . Let  $c_1, c_2, r_1, r_2$  be integers st  $\gcd(r_1, c_1) = \gcd(r_2, c_2) = 1$  and

$$\frac{k_1}{r} = \frac{c_1}{r_1} \quad \text{and} \quad \frac{k_2}{r} = \frac{c_2}{r_2}$$

Then,  $r = \text{lcm}(r_1, r_2)$  with probability at least  $\frac{6}{\pi^2}$ .

Thus

- To obtain  $\frac{c_1}{r_1}$  from  $\tilde{\phi}_k$ , i.e. the nearest fraction approximating  $\frac{k}{r}$  up to some precision dependent on the number of qubits used, one resorts to the [continued fractions](#) method.
- As a second pair  $(c_2, r_2)$  is needed, the whole algorithm is repeated.

## Finally... the algorithm

In order to obtain the order  $r$ , proceed with the following steps

1. run the **quantum eigenvalue estimation** followed by the **continued fractions algorithm** twice to obtain two reduced fractions  $\frac{k_1}{r_1}$  and  $\frac{k_2}{r_2}$
2. if  $\gcd(k_1, k_2) \neq 1$  repeat previous step else set  $r$  as the least common multiple of  $r_1$  and  $r_2$
3. if  $a^r \pmod{N} \equiv 1$  output  $r$  else go back to step 1

In step 2,

- The probability of  $\gcd(k_1, k_2) = 1$  is  $\geq \frac{1}{4}$ . Hence whole algorithm has **constant probability** of success
- computation of  $\gcd$  and least common multiple has complexity  $O(m^2)$ . Hence the whole algorithm must be efficient.

## Reducing to order-finding

### The odd non-prime-power integer splitting problem

Given an odd integer  $n$ , with at least two distinct prime factors, compute two integers

$$1 < n_1 < n \quad \text{and} \quad 1 < n_2 < n$$

$$\text{st } n = n_1 \times n_2$$

Miller proved in 1975 that this problem **reduces probabilistically** to the **order-finding problem**, all reductions being **classical**: only the **estimation problem** is quantum.

## Reduction to order-finding

- To split  $n$ , choose randomly, with uniform probability, an integer  $a$  and compute its order  $r$  such that  $a$  and  $n$  are coprime (test  $a$  from  $\{2, 3, \dots, n-2\}$ ). If they are not coprime, their greatest common divisor is already a non trivial factor of  $n$ .
- If  $r$  is even (it will be with at least a probability of 0.5),  $a^r - 1$  can be factorized as

$$a^r - 1 = (a^{\frac{r}{2}} - 1)(a^{\frac{r}{2}} + 1)$$

- As  $r$  is the order of  $a$ ,  $n$  divides  $a^r - 1$ , which means  $n$  must share a factor with  $(a^{\frac{r}{2}} - 1)$ , or  $(a^{\frac{r}{2}} + 1)$ , or both.

This factor can be extracted by the Euclides algorithm which efficiently returns  $\text{gcd}(a^r - 1, n)$ .

### Question

But how can be sure such a factor is **non trivial**?

## Reduction to order-finding

- Clearly  $n$  does not divide  $(a^{\frac{r}{2}} - 1)$ .  
Actually, if  $\text{rem}(a^{\frac{r}{2}} - 1, n) = 0$ ,  $\frac{r}{2}$ , rather than  $r$ , would be the order of  $a$ .
- However,  $n$  may divide  $(a^{\frac{r}{2}} + 1)$ , i.e.  $a^{\frac{r}{2}} = 1 \pmod{n}$  and not share any factor with  $(a^{\frac{r}{2}} - 1)$ .

Thus, the reduction is probabilistic according to the following

**Theorem:** Let  $n = p_1^{r_1} \times p_2^{r_2} \times \dots \times p_m^{r_m}$  be the prime factorization of an odd number with  $m \geq 2$ . Then for a random  $a$ , chosen uniformly as before, the probability that its order is even and  $a^{\frac{r}{2}} \neq -1 \pmod{n}$  is at least  $(1 - \frac{1}{2^m}) \geq \frac{9}{16}$ .

For number theoretic results see N. Koblitz. *A Course in Number Theory and Cryptography*, Springer, 1994.

# Shor's algorithm

1. Choose  $1 \leq a \leq n - 1$  randomly.
2. If  $\gcd(a, n) > 1$ , then return  $\gcd(a, n)$ .
3. If  $\gcd(a, n) = 1$ , then use the **order-finding** algorithm to compute  $r$  — the order of  $a$  wrt  $n$ .
4. If  $r$  is odd or  $a^{\frac{r}{2}} \equiv -1 \pmod{n}$   
then return to 1.  
else return  $\gcd(a^{\frac{r}{2}} - 1, n)$  and  $\gcd(a^{\frac{r}{2}} + 1, n)$ .

# Shor's algorithm

Shor's approach to **estimate a random integer multiple of  $\frac{1}{r}$**  in his original paper was different from the one discussed in this lecture, as an application of the **eigenvalue estimation algorithm**.

## Shor's approach (based on period finding)

- Create a state

$$\sum_{x=0}^{2^n-1} \frac{1}{\sqrt{2^n}} |x\rangle |\text{rem}(a^x, n)\rangle$$

which is shown to be re-written as

$$\sum_{b=0}^{r-1} \left( \frac{1}{\sqrt{2^n}} \sum_{z=0}^{m_b-1} |zr + b\rangle \right) |\text{rem}(a^x, n)\rangle$$

where  $m_b$  is the largest integer st  $(m_b-1)r + b \leq 2^n - 1$ .

# Shor's algorithm

## Shor's approach (based on period finding)

- Measuring the target register yields  $\text{rem}(a^b, n)$  for  $b$  chosen uniformly at random from  $\{0, 1, 2, \dots, r-1\}$ , and leaves the control register in

$$\frac{1}{\sqrt{m_b}} \sum_{z=0}^{m_b-1} |zr + b\rangle$$

- Apply  $QFT_{2^n}^{-1}$  to the control register

Note that, if  $r, m_b$  were known (!), applying  $QFT_{m_b r}^{-1}$  would lead to

$$\sum_{j=0}^{r-1} e^{-i2\pi \frac{b}{r} j} |m_b j\rangle$$

i.e. only values  $x$  such that  $\frac{x}{rm_b} = \frac{j}{r}$  would be measured.

- Measure  $x$  and output  $\frac{x}{2^n}$ .

# Shor's algorithm

Note that in both approaches the circuit is the **same**.

The only difference is the **basis** in which the state of the system is analysed:

- the eigenvector basis
- the computational basis in Shor's original algorithm.

Shor's original algorithm is based on the **period finding algorithm**, which is another application of phase estimation (see [Nielsen & Chuang, 2010] for a complete account)

In all cases, the underlying quantum component is, of course, the **QFT**.

# Quantum algorithms

Recall the overall idea:

engineering quantum effects as computational resources

## Classes of algorithms

- Algorithms with superpolynomial speed-up, typically based on the quantum Fourier transform, include Shor's algorithm for prime factorization. The level of resources (qubits) required is not yet currently available.
- Algorithms with quadratic speed-up, typically based on amplitude amplification, as in the variants of Grover's algorithm for unstructured search. Easier to implement in current NISQ technology, typical component of other algorithms.
- Quantum simulation

... and we are done!

## Where to look further

- Quantum computation is an extremely **young and challenging** area, looking for young people either with a **theoretical** or **experimental** profile.  
**Get in touch** if you are interested in pursuing studies/research in the area at UMinho, INESC TEC and INL.
- Follow-up courses next semester on

## Continued Fractions

Method to approximate any real number  $t$  with a sequence of rational numbers of the form

$$[a_0, a_1, \dots, a_p] \text{ defined by } a_0 + \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{\dots + \frac{1}{a_p}}}}$$

computed inductively as follows

$$\begin{aligned} a_0 &= \lfloor t \rfloor & r_0 &= t - a_0 \\ a_j &= \left\lfloor \frac{1}{r_{j-1}} \right\rfloor & r_j &= \frac{1}{r_{j-1}} - \left\lfloor \frac{1}{r_{j-1}} \right\rfloor \end{aligned}$$

The sequence  $[a_0, a_1, \dots, a_p]$  is called the  **$p$ -convergent** of  $t$ .

If  $r_p = 0$  the continued fraction terminates with  $a_p$  and

$$t = [a_0, a_1, \dots, a_p],$$

# Continued Fractions

Example:  $\frac{47}{13} = [3, 1, 1, 1, 1, 2]$

$$\begin{aligned} \frac{47}{13} &= 3 + \frac{8}{13} = 3 + \frac{1}{\frac{13}{8}} \\ &= 3 + \frac{1}{1 + \frac{5}{8}} = 3 + \frac{1}{1 + \frac{1}{\frac{8}{5}}} \\ &= 3 + \frac{1}{1 + \frac{1}{1 + \frac{3}{5}}} = 3 + \frac{1}{1 + \frac{1}{1 + \frac{1}{\frac{5}{3}}}} \\ &= 3 + \frac{1}{1 + \frac{1}{1 + \frac{1}{1 + \frac{2}{3}}}} = 3 + \frac{1}{1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{2}}}}} \end{aligned}$$

# Continued Fractions

**Theorem:** The expansion **terminates** iff  $t$  is a **rational** number.

[which makes continued fractions the *right*, finite expansion for rational numbers, differently from decimal expansion]

**Theorem:**  $[a_0, a_1, \dots, a_p] = \frac{p_j}{q_j}$  where

$$p_0 = a_0, q_0 = 1$$

$$p_1 = 1 + a_0 a_1$$

$$p_j = a_j p_{j-1} + p_{j-2}, \quad q_j = a_j q_{j-1} + q_{j-2}$$

**Theorem:** Let  $x$  and  $\frac{p}{q}$  be rationals st

$$\left| x - \frac{p}{q} \right| \leq \frac{1}{2q^2}.$$

Then,  $\frac{p}{q}$  is a convergent of the continued fraction for  $x$ .
