Generalising Grover for multiple solutions ${\scriptstyle \bullet 0 0 0 0 0}$

Amplitude amplification

Exercise 0

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Recall Grover's iterator $G = WU_f$

Question

Can Grover's algorithm be generalised to search in contexts with multiple solutions?

Generalising Grover for multiple solutions 00000

Amplitude amplification

Exercise 0

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Multiple solutions

Assume there are M (out of $2^n = N$) input strings evaluating to 0 by f

$$|\psi\rangle = \frac{1}{\sqrt{N}} \sum_{x=0}^{N-1} |x\rangle = \underbrace{\sqrt{\frac{M}{N}} |s\rangle}_{\text{solution}} + \underbrace{\sqrt{\frac{N-M}{N}} |r\rangle}_{\text{the rest}}$$

where

$$|s
angle = rac{1}{\sqrt{M}} \sum_{x \text{ solution}} |x
angle \text{ and } |r
angle = rac{1}{\sqrt{N-M}} \sum_{x \text{ no solution}} |x
angle$$

Generalising Grover for multiple solutions ${\rm OO}{\bullet}{\rm OOO}$

Amplitude amplification

Exercise 0

Multiple solutions

$$t = \left| \frac{\frac{\pi}{2} - \arcsin \sqrt{\frac{M}{N}}}{2\theta} \right|$$

which, for N large, $M \ll N$ (thus $\theta \approx \sin \theta$), yields

$$t \approx \frac{\pi}{4}\sqrt{\frac{N}{M}}$$

The probability to retrieve a correct solution is

$$|\langle s|G^t|\psi\rangle|^2 \ge \cos^2\theta = 1-\sin^2\theta = \frac{N-M}{N}$$

which, for $M = \frac{N}{2}$ yields $\frac{1}{2}$, but for $M \ll N$, is again close to 1.

Amplitude amplification

Exercise 0

Multiple solutions

Surprisingly, the rotation in each iteration decreases from $M = \frac{N}{2}$ to N, and the number of iterations consequently increases, although one would expect to be easier to find a correct solution if their number increases!

Solution: resort to draft paper!

To double the number of elements in the search space, by adding N extra elements, none of which being a solution.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ● ●

The technique: Amplitude amplification

Grover's algorithm made use of

 $H^{\otimes n}|0\rangle$

to prepare a uniform superposition of potential solutions.

In general, one may resort to any program K to map the solution space to any superposition of guesses, plus some extra qubits to be used as draft paper:

$$\frac{K|0}{2} = \sum_{x} \alpha_{x} |x\rangle |\mathsf{draft}(x)\rangle$$

The technique: Amplitude amplification

$$\left|\psi\right\rangle \;=\; \sum_{x \text{ solution}} \alpha_x |x\rangle \, |\mathsf{draft}(x)\rangle \;\; + \sum_{x \text{ no solution}} \alpha_x |x\rangle \, |\mathsf{draft}(x)\rangle$$

yielding the following probabilities:

$$p_s = \sum_{x \text{ solution}} |lpha_x|^2$$
 and $p_{ns} = \sum_{x \text{ no solution}} |lpha_x|^2 = 1 - p_s$

Of course, amplification has no use if $p_s \in \{0, 1\}$.

▲□▶▲□▶▲≡▶▲≡▶ ≡ めぬぐ

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

The technique: Amplitude amplification

Otherwise ($0 < p_s < 1$), the amplitudes of solution inputs should be amplified.

First, express

$$|\psi
angle \;=\; \sqrt{
ho_{s}}|\psi_{s}
angle \;+\; \sqrt{
ho_{ns}}|\psi_{ns}
angle$$

for the normalised components

$$\begin{array}{l} |\psi_s\rangle \ = \ \sum_{x \text{ solution }} \frac{\alpha_x}{\sqrt{\rho_s}} |x\rangle \, | \mathrm{draft}(x) \rangle \\ |\psi_{ns}\rangle \ = \ \sum_{x \text{ solution }} \frac{\alpha_x}{\sqrt{\rho_{ns}}} |x\rangle \, | \mathrm{draft}(x) \rangle \end{array}$$

which rewrites to

$$|\psi\rangle~=~\sin\theta|\psi_s
angle~+~\cos\theta|\psi_{\it ns}
angle$$

for $\theta \in [0, \frac{\pi}{2}]$ such that $\sin^2 \theta = p_s$.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

The technique: Amplitude amplification

A generic search iterator is built as

$$S = K P K^{-1} V = W_K V$$

where

 $egin{array}{lll} W_{\mathcal{K}}|\psi
angle &= |\psi
angle \\ W_{\mathcal{K}}|\phi
angle &= -|\phi
angle & ext{for all states orthogonal to }|\psi
angle \end{array}$

The sets $\{|\psi_s\rangle, |\psi_{ns}\rangle\}$ and $\{|\psi\rangle, |\overline{\psi}\rangle\}$ are bases for the relevant 2-dimensional subspace.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ● ●

The technique: Amplitude amplification

As expected, starting in $|\psi\rangle,$ the oracle produces

 $-\sin\theta|\psi_s\rangle + \cos\theta|\psi_{ns}\rangle = \cos(2\theta)|\psi\rangle - \sin(2\theta)|\overline{\psi}\rangle$

which, followed by the amplifier, yields

 $\cos(2\theta)|\psi\rangle+\sin(2\theta)|\overline{\psi}\rangle$

i.e. the effect of iterator S is

 $|\mathbf{S}|\psi\rangle = \cos(2\theta)|\psi\rangle + \sin(2\theta)|\overline{\psi}\rangle$

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

The technique: Amplitude amplification

Exercise

Show that

$$|\mathbf{S}|\psi\rangle = \cos(2\theta)|\psi\rangle + \sin(2\theta)|\overline{\psi}\rangle$$

can be expressed in the basis $\{|\psi_s\rangle, |\psi_{ns}\rangle\}$ as

$$|\Psi\rangle = \sin(3\theta)|\psi_s\rangle + \cos(3\theta)|\psi_{ns}\rangle$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

The technique: Amplitude amplification

$$\begin{split} S|\psi\rangle &= \cos(2\theta)|\psi\rangle + \sin(2\theta)|\overline{\psi}\rangle \\ &= \cos(2\theta)(\sin\theta|\psi_s\rangle + \cos\theta|\psi_{ns}\rangle) + \sin(2\theta)(\cos\theta|\psi_s\rangle - \sin\theta|\psi_{ns}\rangle) \\ &= \cos(2\theta)(\sin\theta|\psi_s\rangle + \cos(2\theta)\cos\theta|\psi_{ns}\rangle + \sin(2\theta)\cos\theta|\psi_s\rangle - \sin(2\theta)\sin\theta|\psi_{ns}\rangle \\ &= (\cos(2\theta)\sin\theta + \sin(2\theta)\cos\theta)|\psi_s\rangle + (\cos(2\theta)\cos\theta - \sin(2\theta)\sin\theta)|\psi_{ns}\rangle \\ &= ((\cos^2\theta - \sin^2\theta)\sin\theta + \sin(2\theta)\cos\theta)|\psi_s\rangle + ((\cos^2\theta - \sin^2\theta)\cos\theta - \sin(2\theta)\sin\theta)|\psi_{ns}\rangle \\ &= (\cos^2\theta\sin\theta - \sin^2\theta\sin\theta + \sin(2\theta)\cos\theta)|\psi_s\rangle + (\cos^2\theta\cos\theta - \sin^2\theta\cos\theta - \sin(2\theta)\sin\theta)|\psi_{ns}\rangle \\ &= (\cos^2\theta\sin\theta - \sin^3\theta + 2\sin\theta\cos^2\theta)|\psi_s\rangle + (\cos^3\theta - \sin^2\theta\cos\theta - 2\sin^2\theta\cos\theta)|\psi_{ns}\rangle \\ &= (\cos^2\theta\sin\theta - \sin^3\theta + 2\sin\theta\cos^2\theta)|\psi_s\rangle + (\cos^3\theta - \sin^2\theta\cos\theta - 2\sin^2\theta\cos\theta)|\psi_{ns}\rangle \\ &= (3\cos^2\theta\sin\theta - \sin^3\theta)|\psi_s\rangle + (\cos^3\theta - 3\sin^2\theta\cos\theta)|\psi_{ns}\rangle \\ &= (3\cos^2\theta\sin\theta - \sin^3\theta)|\psi_s\rangle + (\cos^3\theta - 3(1 - \cos^2\theta)\cos\theta)|\psi_{ns}\rangle \\ &= (3\sin\theta - 3\sin^3\theta - \sin^3\theta)|\psi_s\rangle + (\cos^3\theta - 3\cos\theta + 3\cos^2\theta)|\psi_{ns}\rangle \\ &= (3\sin\theta - 4\sin^3\theta)|\psi_s\rangle + (4\cos^3\theta - 3\cos\theta)|\psi_{ns}\rangle \\ &= \sin(3\theta)|\psi_s\rangle + \cos(3\theta)|\psi_{ns}\rangle \end{split}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ● ●

The technique: Amplitude amplification

By an inductive argument, the repeated application of S a total of k times rotates the initial state $|\psi\rangle$ to

```
S^{k}|\psi\rangle = \sin((2k+1)\theta)|\psi_{s}\rangle + \cos((2k+1)\theta)|\psi_{ns}\rangle
```

For the correct number of iterations, this procedure reaches a state such that a measurement will return an element of the subspace spanned by $|\psi_s\rangle$ with a probability close to 1.

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

The technique: Amplitude amplification

As before, to get that high probability, the smallest value for k one can choose is such that

$$(2k+1)\theta \approx \frac{\pi}{2}$$

For a small θ , as

$$\sin \theta = \sqrt{p_s} \approx \theta$$

the magnitude of the right number of iterations is

$$O\left(\sqrt{\frac{1}{\theta}}\right)$$

because

$$(2k+1)\sqrt{p_s} = \theta \Leftrightarrow k = \frac{\pi}{4\sqrt{p_s}} - \frac{1}{2}$$

To follow

The algorithm requires that one knows in advance how many times iterator S is to be applied:

- For K = H (uniform sampling the input) this boils down to know the number of solutions of the search problem.
- For a generic K this amounts to know the probability with which K guesses a solution to the problem, i.e. $\sin(\theta)$.

To see ...

- blind search
- estimate the amplitude with which K maps |0> to the subspace of solutions

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Exercise

Consider a search space N = 4, with M = 2.

- How many iterations are required to find the correct solution with high probability? Why? Which is the angle of the rotation in each iteration?
- How many queries to the oracle would be necessary under a classical computer?
- Discuss whether the circuit below performs the phase shift operation $2|0\rangle\langle 0| I$, up to an irrelevant global phase factor.

• Prove the Grover iterator G is, as expected, unitary.
